

### QUESTION

Let  $n = q_1 q_2 \dots q_k$  where the  $q_i$  are distinct primes and  $k > 1$ . Show that if  $n$  is a Carmichael number then  $q_i - 1 | n - 1$  for each  $i$ . (This is the converse of the result you proved in example sheet 4, no. 5). Hence show that there is no Carmichael number of the form  $3 \cdot 5 \cdot q$ , where  $q$  is any prime  $> 5$ .

### ANSWER

Suppose  $n$  is a Carmichael number. Then, for any  $b$  satisfying  $\gcd(b, n) = 1$ , we have  $b^{n-1} \equiv 1 \pmod{n}$ . Now  $q_i$  is prime, so we can find a primitive element  $g_i$  say mod  $q_i$ . The  $q_i$  are distinct, so the Chinese Remainder Theorem allows us to find a unique solution mod  $n$  to the simultaneous congruences  $x \equiv g_i \pmod{q_i}$  for  $1 \leq i \leq k$ . Let  $b$  be this unique solution. The  $\gcd(b, n) = 1$  since  $\gcd(b, q_i) = 1$  for each  $i$ . Thus  $b^{n-1} \equiv 1 \pmod{n}$ , and so  $b^{n-1} \equiv 1 \pmod{q_i}$  for each  $i$ . But  $b \equiv g_i \pmod{q_i}$ , and  $g_i$  has order  $q_i - 1 \pmod{q_i}$  as  $g_i$  is a primitive element mod  $q_i$ . Thus  $q_i - 1 | n - 1$ , and this is true for each  $i$ , as required.

Now suppose  $n = 3 \cdot 5 \cdot q$  is a Carmichael number, where  $q$  is a prime  $> 5$ . By the above,  $n$  is divisible by  $2 \cdot 4$  and  $q - 1$ . Set  $q - 1 = t$ . Then  $n = 15(t + 1)$ , so  $n - 1 = 15t + 14$ . Since  $t | n - 1$  we have  $t | 14$ . Thus  $t = 1, 2, 7$  or  $14$ , which makes  $q = t + 1$  equal to  $2, 3, 8$  or  $25$ , none of which is a prime  $> 5$ . Thus no such Carmichael number exists.
